SONY

CXA1690Q

Head Amplifier for Digital CCD Cameras

Description

The CXA1690Q is a bipolar IC developed as a head amplifier for digital CCD cameras. The CXA1690Q provides the following functions: correlated double sampling, AGC for CCD signals, GCA for chroma signals, GCA for line signals, sample and hold for A/D converters, blanking, and reference voltage output/output driver for A/D converters.

Features

- Permits higher sensitivity with a high-gain AGC amplifier
- Blanking function for the purpose of calibrating the deviation in black levels of the CCD output signals
- · Permits output offset adjustment
- Provides a regulator output pin for the reference voltage for A/D converters
- Built-in GCA that amplifies video signals (chroma and line signals) from an external source
- Built-in sample-and-hold circuits (for both camera signals and video signals) required by external A/D converters

Absolute Maximum Ratings

 Supply voltage 	Vcc	14	V
 Operating temperature 	Topr	-20 to +75	°C
 Storage temperature 	Tstg	-65 to +150	°C
Allowable power dissipation	PD	460	mW

Operating Conditions

Electrical Characteristics Measurement Circuit

Application Circuit

Description of Operation

1. Camera signal processing system

Operating conditions

The camera signal processing system operates when CAM/VIDEO is High, and PB/REC is Low.

Camera Signal Processing System Timing Chart

CDS:

The CCD signal from the CCD image sensor enters PIN and DIN where it is correlated double sampled (CDS: Correlated Double Sampling) by SH1, SH2 and SH3. The precharge level of the CCD output signal is sampled-and-held and output by the SH2 output, and the signal level is sampled-and-held and output by the SH3 output.

CDSCLP:

The CDSCLP stabilizes the DC level of the input signal, clamps (CLPDM) the input signal during the dummy pixel interval for the purpose of eliminating the AGC input offset, and combines the DC level ([*1], [*2]) of SH2 and SH3.

AGC:

The gain can be varied with the AGCMAX and AGCCONT voltage control (20/50) Vcc to Vcc. The maximum gain can be varied from 19 to 43dB for AGCMAX, and from 7.9 to 43dB for AGCCONT.

LPF:

A primary low-pass filter has been installed for the purpose of eliminating unused bands and white noise and improving S/N.

CAMSH:

The CAMSH is used for camera system signal processing. It is a sample-and-hold circuit which synchronizes the data read-in timing for the external A/D. The slew rate of the input signal for the sample-and-hold circuit can be controlled by adjusting the input current to the CSHI pin.

AGCCLP:

The basic black level is set ([*3]) by clamping it with the CLPOB clock during the OPB interval of the AGC output waveform. The capacitance for AGCCLP is connected to the AGCCLP pin.

BLK:

The black level is calibrated by blanking the black level signal of the AGC output waveform so that it does not fall below the basic black level and replacing the DC potential. ([*4]) The signal is blanked when PBLK is low.

C/VSW:

When the CAM/VIDEO and PB/REC pin voltages are set so that the camera signal processing system operates, C/VSW leads the BLK output (camera signal) into the DRV. In addition, when these voltages are set so that the video signal processing system operates, C/VSW leads the VISH output (video signal) into the DRV.

CLPSW:

By selecting the CAM/VIDEO and PB/REC pin voltages, either [CAMCLP] is connected and lead into the CLPDRV pin as the clamp for the output signal of the camera signal processing system, or [LOUTCLP] as the clamp for the LIN mode output signal or [RFDC] as the DC shift for the PBREC mode output signal of the video signal processing system.

DRV:

DRV drives the external A/D. RF mode or LIN mode signals for either the camera or video signals are input to the DRV and output from DRVOUT by switching C/VSW.

CAMCLP:

The signal black level interval is clamped by the CLPDM clock to bring camera system signals within the allowable input voltage range for the external A/D, and the signals are output to CLPOUT. ([*5]) In addition, the CAMCLP contains an OFFSET control pin which adjusts the CLP potential for the purpose of compensating the clamp level difference generated by the DRV.

REFBOTTOM, REFTOP:

REFBOTTOM and REFTOP are reference voltage source for the external A/D. They are connected to VRB and VRT, and supply 2V and 4V to the A/D.

2. Video signal processing system

Operating conditions

The video signal processing system has two modes: LIN signal mode and PBREC signal mode.

The video signal processing system operates in LIN signal mode when CAM/VIDEO is Low, and PB/REC is High.

The video signal processing system operates in PBREC signal mode when PB/REC is High.

Video Signal Processing System Timing Chart

LIN signal mode

LINCLP:

The video signal enters the LIN pin. LINCLP sync tip clamps the input signal to allow full input. The input signal level and frequency are respectively 500 mVp-p (typ.) and DC up to approx. 7MHz.

LINAMP:

This is a 9.5dB gain amplifier.

VISW:

VISW switches between the LIN signal and PBRFC signal for the video signal processing system. The signals are switched according to the input conditions of the CAM/VIDEO and PB/REC pins.

VISH:

The VISH is used for video signal processing system. It is a sample-and-hold circuit which synchronizes the data read-in timing for the external A/D. The slew rate of the input signal for the sample-and-hold circuit can be controlled by adjusting the input current to VSHI.

LOUTCLP:

LOUTCLP is a clamp circuit which operates when the LIN signal is output by the DRV. The clamp potential is 2V.

PBREC signal mode

RFGCA:

This is an amplifier which controls the gain of the video chroma RF signal input to PBRFC. The RFCONT voltage can be varied from (20/50) Vcc to Vcc, enabling the gain to be varied from 0.5 to 17dB. The input signal level and frequency are respectively 200mVp-p (typ.) and DC up to approx. 1.5MHz.

RFDC:

RFDC is a DC bias circuit which operates when the PBREC signal is output by the DRV. The DC bias potential is 3V.

PBREC mode
