

150 MHz Differential Twisted Pair Driver

#### **Features**

- Fully differential inputs, outputs, and feedback
- Differential input range ±2.3V
- 150 MHz 3 dB bandwidth
- 800 V/µs slew rate
- −55 dB distortion at 3 MHz
- −75 dB distortion at 100 kHz
- ±5V supplies or +6V single supply
- 50 mA minimum output current
- Output swing (200Ω load) to within 1.5V of supplies (14V pk-pk differential)
- Low power-11 mA typical supply current

#### **Applications**

- Twisted pair driver
- Differential line driver
- VGA over twisted pair
- ADSL/HDSL driver
- Single ended to differential amplification
- Transmission of analog signals in a noisy environment

#### **Ordering Information**

Part No.	Temp. Range	Package	Outline #
EL2140CN	-40°C to +85°C	8-pin PDIP	MDP0031
EL2140CS	-40°C to +85°C	8-pin SOIC	MDP0027
EL2141CN	-40°C to +85°C	8-pin PDIP	MDP0031
EL2141CS	-40°C to +85°C	8-pin SOIC	MDP0027

#### General Description

The EL2140C/2141C is a very high bandwidth amplifier whose output is in differential form, and is thus primarily targeted for applications such as driving twisted pair lines, or any application where common mode injection is likely to occur. The input signal can be in either single-ended or differential form, but the output is always in differential form.

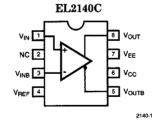

On the EL2141C, two feedback inputs provide the user with the ability to set the device gain, (stable at minimum gain of two), whereas the EL2140C comes with a fixed gain of two.

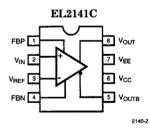

The output common mode level is set by the reference pin  $(V_{REF})$ , which has a -3 dB bandwidth of over 100 MHz. Generally, this pin is grounded, but it can be tied to any voltage reference.

The transmission of ADSL/HDSL signals requires very low distortion amplification, so this amplifier was designed with this as a primary goal. The actual signal distortion levels depend upon input and output signal amplitude, as well as the output load impedance. (See distortion data inside.)

Both outputs (V<sub>OUT</sub>, V<sub>OUTB</sub>) are short circuit protected to withstand temporary overload condition.

Important Note:

All parameters having Min/Max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality inspection. Elantec performs most electrical tests using modern high-speed automatic test equipment, specifically the LTX77 Series system. Unless otherwise noted, all feets are pulsed tests, therefore  $T_A - T_C = T_A$ .

### **Applications Information**

$$GAIN = \frac{R1 + R2 + R3}{R2}$$

#### Choice of feedback resistor

There is little to be gained from choosing resistor R2 values below  $400\Omega$  and, in fact, it would only result in increased power dissipation and signal distortion. Above  $400\Omega$ , the bandwidth response will develop some peaking (for a gain of two), but substantially higher resistor R2 values may be used for higher voltage gains, such as up to  $2 k\Omega$  at a gain of eight before peaking will develop. R1 and R3 are selected as needed to set the voltage

gain, and while R1 = R3 is suggested, the gain equation above holds for any values (see distor-

### Capacitance considerations

tion for further suggestions).

As with many high bandwidth amplifiers, the EL2140C/2141C prefer not to drive highly capacitive loads. It is best if the capacitance on V<sub>OUT</sub> and V<sub>OUTB</sub> is kept below 10 pF if the user does not want gain peaking to develop.

In addition, on the EL2141C, the two feedback nodes FBP and FBN should be laid out so as to minimize stray capacitance, else an additional pole will potentially develop in the response with possible gain peaking.

The amount of capacitance tolerated on any of these nodes in an actual application will also be dependent on the gain setting and the resistor values in the feedback network.

### Distortion considerations

The harmonics that these amplifiers will potentially produce are the 2nd, 3rd, 5th, and 6th. Their amplitude is application dependent. All other harmonics should be negligible by comparison. Each should be considered separately:

H2 The second harmonic arises from the input stage, and the lower the applied differential signal amplitude, the lower the magnitude of the second harmonic. For practical considerations of required output signal and input noise levels, the user will end up choosing a circuit gain. Referring to Figure 1, it is best if the voltage at the negative feedback node tracks the  $V_{REF}$  node, and the voltage at the positive feedback node tracks the  $V_{IN}$  node respectively. This would theoretically require that R1 + R2 = R3, although the lowest distortion is found at about R3 = R1 + (0.7\*R2). With this arrangement, the second harmonic should be suppressed well below the value of the third harmonic.

## 150 MHz Differential Twisted Pair Driver

#### Applications Information - Contd.

H3 The third harmonic should be the dominant harmonic and is primarily affected by output load current which, of course, is unavoidable. However, this should encourage the user not to waste current in the gain setting resistors, and to use values that consume only a small proportion of the load current, so long as peaking does not occur. The more load current, the worse the distortion, but depending on the frequency, it may be possible to reduce the amplifier gain so that there is more internal gain left to cancel out any distortion.

H5 The fifth harmonic should always be below the third, and will not become significant until heavy load currents are drawn. Generally, it should respond to the same efforts applied to reducing the third harmonic.

H6 The sixth harmonic should not be a problem and is the result of poor power supply decoupling. While 100 nF chip capacitors may be sufficient for some applications, it would be insufficient for driving full signal swings into a twisted pair line at 100 kHz. Under these conditions, the addition of 4.7 µF tantalum capacitors would cure the problem.

### Soldering Packages to PC Boards

#### **DIP Packages**

Wave soldering is recommended for DIP packages. Solder plated boards are recommended. Rosin mildly activated (RMA) flux is needed. Wave soldering using a dual wave system at 250°C ±10°C for two seconds per wave is preferable. Thorough cleaning of boards after soldering is required.

Hand soldering, Elantec's DIP packages will survive a peak temperature of 300°C (at leads) for a maximum period of 10 seconds.

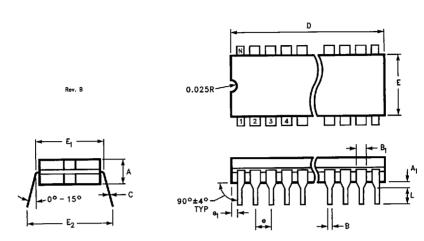

### **Surface Mount Packages**

Wave soldering and vapor phase or infrared (IR) reflow can be used for soldering surface mount packages to PC boards. Solder plated boards are recommended for wave soldering and vapor phase or IR reflow methods.

Wave Soldering: Adhesive is used to hold components on the boards during wave soldering. Place components on the board and cure adhesive before wave soldering. Rosin mildly activated (RMA) flux or organic flux is needed. Wave soldering using a dual wave system at 250°C ±10°C for a maximum of two seconds per wave is preferable. Thorough cleaning of boards after soldering is required.

Reflow Soldering: Screen solder paste on board and attach components to board. Solder paste with RMA flux is recommended. Bake boards at 65°C-90°C for 15 minutes. Preheat boards to within 60°C-70°C of the solder temperature. To reflow solder paste with vapor phase method, the solder paste temperature must be maintained at or above 200°C for at least 30 seconds. The components temperature can not exceed 215°C. For the IR reflow method, the solder paste temperature must be maintained at or above 200°C for at least 30 seconds. The components temperature can not exceed 220°C. The temperature/time ramp-up during vapor phase or IR reflow shall be no greater than 2°C/sec.

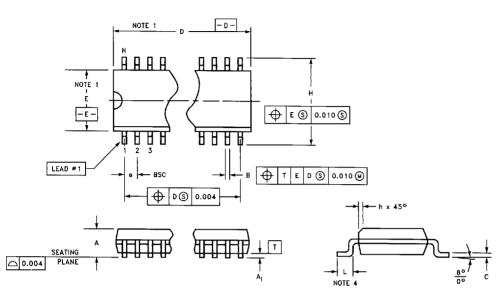

Hand soldering, Elantec's surface mount packages will survive a peak temperature of 260°C (at leads) for a maximum period of 10 seconds.
