## SAMPLE/HOLD AMPLIFIER

### FEATURES

- FAST (6 $\mu$ s max) ACQUISITION TIME (14-bit)
- APERTURE JITTER 400ps
- POWER DISSIPATION: 300mW
- COMPATIBLE WITH HIGH RESOLUTION A/D CONVERTERS ADC76, PCM75, AND ADC71

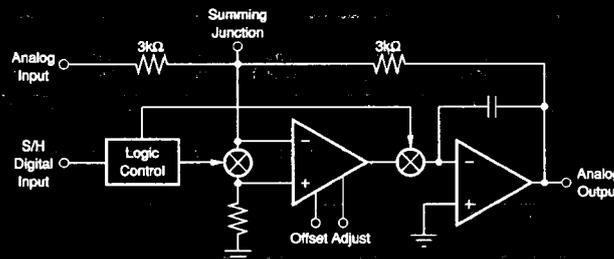

### DESCRIPTION

The SHC76 is fast, high-accuracy hybrid sample/hold circuit suitable for use in high-resolution data acquisition systems.

The SHC76 is complete with internal hold capacitor and incorporates an internal compensation network which minimizes sample-to-hold charge offset. The SHC76 is configured as a unity-gain inverter.

High-resolution converters such as the ADC76 and ADC71 are compatible with SHC76 in forming complete, 14-bit accurate analog-to-digital conversion systems.

The SHC76 comes in a 14-pin single-wide hermetic metal DIP. Power supply requirements are specified from  $\pm 14.5V$  to  $\pm 15.5V$  with guaranteed operation from  $\pm 11.4V$  to  $\pm 18V$ . Input voltage range is  $\pm 10V$ . The SHC76 is available in two temperature ranges: KM, for  $0^{\circ}C$  to  $+70^{\circ}C$ ; and BM, for  $-25^{\circ}C$  to  $+85^{\circ}C$  operation.

CAUTION: These devices are sensitive to electrostatic discharge. Appropriate I.C. handling procedures should be followed.

NOTES: (1) Absolute maximum ratings are limiting values, applied individually, beyond which the servability of the circuit may be impaired. Functional operation under any of these conditions is not necessarily implied. (2) Internal power dissipation may limit output current to less than +20mA. (3) WARNING: This device cannot withstand even a momentary short circuit to either supply.

## DISCUSSION OF SPECIFICATIONS

### THROUGHPUT NONLINEARITY

This is defined as total Hold mode, nonadjustable, input to output error caused by charge offset, gain nonlinearity, droop, feedthrough, and thermal transients. It is the inaccuracy due to these errors which cannot be corrected by Offset and Gain adjustments.

### GAIN ERROR

The difference between the input and output voltage magnitude (in the Sample mode) due to the amplifier gain errors.

### DROOP RATE

The voltage decay at the output when in the Hold mode due to storage capacitor and FET switch leakage current and the input bias current of the output amplifier.

### FEEDTHROUGH

The amount of output voltage change caused by an input voltage change when the sample/hold is in the Hold mode.

### APERTURE DELAY TIME

The time required to switch from Sample to Hold. The time is measured from the 50% point of the Hold mode control transition to the time at which the output stops tracking the input.

### APERTURE UNCERTAINTY TIME

The nonrepeatability of aperture delay time.

### ACQUISITION TIME

The time required for the sample/hold output to settle within a given error band of its final value when the sample/hold is switched from Hold to Sample.

### CHARGE OFFSET (PEDESTAL)

The output voltage change that results from charge coupled into the Hold capacitor through the gate capacitance of the switching field effect transistor. This charge appears as an offset at the output.

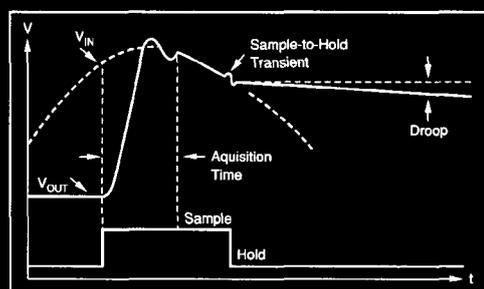

FIGURE 1. Definition of Acquisition Time, Droop and Sample-to-Hold Transient.

### SAMPLE-TO-HOLD SWITCHING TRANSIENT

The switching transient which appears on the output when the sample/hold is switched from Sample to Hold. Both the magnitude and the settling time of the transient are specified.

### SAMPLED DATA ACQUISITION SYSTEM CALCULATIONS

The rated accuracy of an A/D converter in combination with the aperture uncertainty of a sample/hold determine the maximum theoretical input slew rate (frequency) of a given sampled data system.

$$\text{Sine Wave } f_{\text{MAX}} = (2^{-N} \text{FSR}) + (2\pi A t)$$

A = max Input Signal Amplitude (peak-to-peak)  
 FSR = Full-Scale Range of A/D Converter  
 t = Aperture Uncertainty of S/H (jitter)  
 N = Number of Bits Accuracy

Given below are the maximum input frequencies of two A/D converters in conjunction with the SHC76:

$$\text{SHC76 13-bit Sine Wave } f_{\text{MAX}} = (0.000122 \cdot 20V) + (2 \cdot \pi \cdot 20V \cdot 0.4\text{ns}) = 48.6\text{kHz}$$

$$\text{SHC76 14-bit Sine Wave } f_{\text{MAX}} = (0.000061 \cdot 20V) + (2 \cdot \pi \cdot 20V \cdot 0.4\text{ns}) = 24.3\text{kHz}$$

The maximum throughput rate is determined by adding all critical conversion process times together. Throughput rate cannot exceed the maximum input frequency determined by the accuracy and jitter specs without degrading system performance. Two samples per period of a sine wave are required to satisfy the Nyquist sampling theorem. A low-pass filter is required to cut off frequencies higher than the maximum throughput frequency to prevent aliasing errors from occurring.

$$\text{Throughput } f_{\text{MAX}} (2 \text{ samples}) = 1 + [2 (\text{S/H acquisition time} + \text{S/H settling time} + \text{A/D conversion time})]$$

Table I is a listing of various A/D throughput rates using the SHC76 S/H amplifier (assuming two samples per period).
